## Problem Setting and Related Work

Proposed algorithm

Empirical results

Discussion and Conclusions

# Problem: unsupervised changepoint detection

- ▶ We are given a data sequence  $z_1, \dots, z_T$  measured at  $T$  points over time/space.
- ▶ Ex: DNA copy number data for cancer diagnosis,  $z_t \in \mathbb{R}$ .
- ▶ The penalized changepoint problem is

$$\arg \min_{u_1, \dots, u_T \in \mathbb{R}} \sum_{t=1}^T (u_t - z_t)^2 + \lambda \sum_{t=2}^T I[u_{t-1} \neq u_t].$$

Larger penalty  $\lambda$  results in fewer changes/segments.

Smaller penalty  $\lambda$  results in more changes/segments.

# Problem: weakly supervised changepoint detection

- ▶ We are given a data sequence  $\mathbf{z}$  with labeled regions  $L$ .
- ▶ We compute features  $\mathbf{x} = \phi(\mathbf{z}) \in \mathbf{R}^p$  and want to learn a function  $f(\mathbf{x}) = -\log \lambda \in \mathbf{R}$  that minimizes label error.

# Problem: supervised binary classification

- ▶ Given pairs of inputs  $\mathbf{x} \in \mathbb{R}^p$  and outputs  $y \in \{0, 1\}$  can we learn  $f(\mathbf{x}) = y$ ?
- ▶ Example: email,  $\mathbf{x}$  = bag of words,  $y$  = spam or not.
- ▶ Example: images. Jones *et al.* PNAS 2009.

## A Automated Cell Image Processing

Cytoprofile of 500+ features measured for each cell

## B Iterative Machine Learning

System presents cells to biologist for scoring, in batches

# Receiver Operating Characteristic (ROC) curve

- ▶ Binary classification algo gives predictions  $[\hat{y}_1, \hat{y}_2, \hat{y}_3, \hat{y}_4]$ .
- ▶ Each point on the ROC curve is the FPR/TPR if you add some constant  $c$  to the predictions,  $[\hat{y}_1 + c, \hat{y}_2 + c, \hat{y}_3 + c, \hat{y}_4 + c]$ .
- ▶ Best point in ROC space is upper left (0% FPR, 100% TPR).
- ▶ Maximizing Area Under the ROC curve (AUC) is a common objective for binary classification, especially for imbalanced data (example: 99% positive, 1% negative labels).

In binary classification, ROC curve is monotonic increasing.

- ▶ AUC=1 best.
- ▶ AUC=0.5 for constant prediction (usually worst).

# Area Under ROC curve, synthetic example

- ▶ label =  $[1, 0, 0, \dots, 1, 1, 0]$  (20 labels, 10 positive, 10 negative).
- ▶ predictions =  $[-4, -4, -4, \dots, -2, -2, -2]$ .
- ▶ No constant added  $c = 0$ ,  $q = 1$ , everything predicted negative, so no false positives, but no true positives.
- ▶ Add  $c = 3 \Rightarrow [-1, -1, -1, \dots, 1, 1, 1]$ , 1 FP and 9 TP,  $q = 2$ .
- ▶ Add  $c = 5 \Rightarrow [1, 1, 1, \dots, 3, 3, 3]$ , all FP and TP,  $q = 3$ .

Problem Setting and Related Work

Proposed algorithm

Empirical results

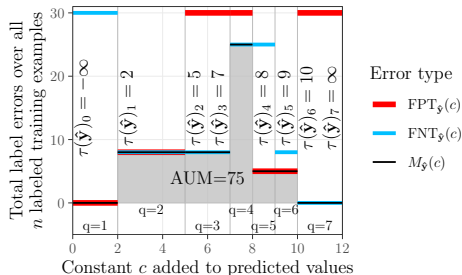

Discussion and Conclusions

# Looping ROC curve, simple synthetic example

If ROC curve has loops, AUC can be greater than one.

- ▶ Dark grey area double counted.
- ▶ Red area negative counted.
- ▶ Do we want to maximize AUC?
- ▶ Minimize Area Under Min (AUM) instead, which encourages ROC points in upper left.

# Real data example with non-monotonic label error

ROC curve loops result from non-monotonic FP/FN functions, but do these occur in real data? Yes, in supervised changepoint problems.

Optimal changepoint model may have non-monotonic error (for example FN), because changepoints at model size  $s$  may not be present in model  $s + 1$ .

# Real data example with AUC greater than one

Error type

FN

FP

- ▶  $n = 2$  labeled changepoint problems.
- ▶  $\text{AUC} = 2$  when prediction difference = 5.
- ▶  $\text{AUM} = 0$  implies  $\text{AUC} = 1$ .
- ▶ AUM is convex relaxation of non-convex Sum of Min (SM).
- ▶ AUM is differentiable almost everywhere.
- ▶ Main new idea: compute the gradient of this function and use it for learning.

# Algorithm inputs: predictions and label error functions

- ▶ Each observation  $i \in \{1, \dots, n\}$  has a predicted value  $\hat{y}_i \in \mathbb{R}$ .
- ▶ Breakpoints  $b \in \{1, \dots, B\}$  used to represent label error via tuple  $(v_b, \Delta FP_b, \Delta FN_b, \mathcal{I}_b)$ .
- ▶ There are changes  $\Delta FP_b, \Delta FN_b$  at predicted value  $v_b \in \mathbb{R}$  in error function  $\mathcal{I}_b \in \{1, \dots, n\}$ .

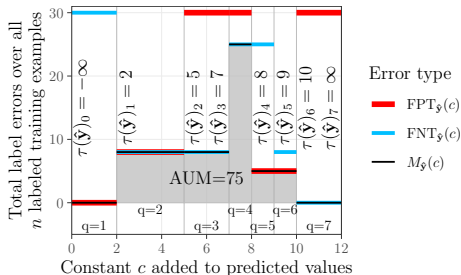

## Algorithm computes total FP and FN for each threshold/constant added to predicted values

- ▶ Breakpoint threshold,  $t_b = v_b - \hat{y}_{\mathcal{I}_b} = \tau(\hat{\mathbf{y}})_q$  for some  $q$ .
- ▶ Total error before/after each breakpoint can be computed via sort and modified cumsum:

$$\underline{\text{FP}}_b = \sum_{j: t_j < t_b} \Delta \text{FP}_j, \quad \overline{\text{FP}}_b = \sum_{j: t_j \leq t_b} \Delta \text{FP}_j,$$

$$\underline{\text{FN}}_b = \sum_{j: t_j \geq t_b} -\Delta \text{FN}_j, \quad \overline{\text{FN}}_b = \sum_{j: t_j > t_b} -\Delta \text{FN}_j.$$

# Algorithm computes two directional derivatives

- ▶ Gradient only defined when function is differentiable, but AUM is not everywhere (see below).
- ▶ Directional derivatives defined everywhere.

$$\nabla_{\mathbf{v}(-1,i)} \text{AUM}(\hat{\mathbf{y}}) =$$

$$\sum_{b:\mathcal{I}_b=i} \min\{\overline{\text{FP}}_b, \overline{\text{FN}}_b\} - \min\{\overline{\text{FP}}_b - \Delta\text{FP}_b, \overline{\text{FN}}_b - \Delta\text{FN}_b\},$$

$$\nabla_{\mathbf{v}(1,i)} \text{AUM}(\hat{\mathbf{y}}) =$$

$$\sum_{b:\mathcal{I}_b=i} \min\{\underline{\text{FP}}_b + \Delta\text{FP}_b, \underline{\text{FN}}_b + \Delta\text{FN}_b\} - \min\{\underline{\text{FP}}_b, \underline{\text{FN}}_b\}.$$

Problem Setting and Related Work

Proposed algorithm

Empirical results

Discussion and Conclusions

# Train set ROC curves for a real changepoint problem

- ▶ Left/middle: changepoint problem initialized to prediction vector with min label errors, gradient descent on prediction vector.
- ▶ Right: linear model initialized by minimizing regularized convex loss (surrogate for label error), gradient descent on weight vector.

# Learning algorithm results in better test AUC/AUM for changepoint problems

- ▶ Five changepoint problems (panels from left to right).
- ▶ Two evaluation metrics (AUM=top, AUC=bottom).
- ▶ Three algorithms (Y axis), Initial=Min regularized convex loss (surrogate for label error),  
Min.Valid.AUM/Min.Valid.AUC=AUM gradient descent with early stopping regularization.

# Standard logistic loss fails for highly imbalanced labels

Comparing logistic regression models (control experiment)

- ▶ Test set has 50% positive, 50% negative labels.
- ▶ Train set has variable class imbalance (panels top to bottom).
- ▶ Loss is  $\ell[f(x_i), y_i]w_i$  with  $w_i = 1$  for identity weights,  $w_i = 1/N_{y_i}$  for balanced, ex: 1% position means  $w_i \in \{1/10, 1/990\}$ .

# Learning algorithm competitive for unbalanced binary classification

(b) AUM compared to baselines

- ▶ Squared hinge all pairs is a classic/popular surrogate loss function for AUC optimization.
- ▶ All linear models with early stopping regularization.

# Error rate loss is not as useful as error count loss

(a) Comparing AUM variants

- ▶ AUM.count is as described previously: error functions used to compute  $\text{Min}(\text{FP}, \text{FN})$  are absolute label counts.
- ▶ AUM.rate is a variant which uses normalized error functions,  $\text{Min}(\text{FPR}, \text{FNR})$ .
- ▶ Both linear models with early stopping regularization.

# Comparable computation time to other loss functions

- ▶ Logistic  $O(n)$ .
- ▶ AUM  $O(n \log n)$ .
- ▶ Squared Hinge All Pairs  $O(n^2)$ .
- ▶ Squared Hinge Each Example  $O(n)$ .

Problem Setting and Related Work

Proposed algorithm

Empirical results

Discussion and Conclusions

# Conclusions, Pre-print arXiv:2107.01285

- ▶ ROC curves are used to evaluate binary classification and changepoint detection algorithms.
- ▶ In changepoint detection there can be loops in ROC curves, so maximizing AUC may not be desirable.
- ▶ Instead we propose to minimize a new loss,  $AUM = \text{Area Under Min}(FP, FN)$ .
- ▶ We propose new algorithm for efficient AUM and directional derivative computation.
- ▶ Empirical results provide evidence that learning using AUM minimization results in AUC maximization.
- ▶ Future work: sort-based surrogates for all pairs loss functions (binary classification, information retrieval).

Thanks!

## More notation

- First let  $\{(\text{fpt}(\hat{\mathbf{y}})_q, \text{fnt}(\hat{\mathbf{y}})_q, \tau(\hat{\mathbf{y}})_q)\}_{q=1}^Q$  be a sequence of  $Q$  tuples, each of which corresponds to a point on the ROC curve (and an interval on the fn/fp error plot).
- For each  $q$  the  $\text{fpt}(\hat{\mathbf{y}})_q, \text{fnt}(\hat{\mathbf{y}})_q$  are false positive/negative totals at that point (in that interval) whereas  $\tau(\hat{\mathbf{y}})_q$  is the upper limit of the interval.
- The limits are increasing,  $-\infty = \tau(\hat{\mathbf{y}})_0 < \dots < \tau(\hat{\mathbf{y}})_Q = \infty$ .
- Then we define  $m(\hat{\mathbf{y}})_q = \min\{\text{fpt}(\hat{\mathbf{y}})_q, \text{fnt}(\hat{\mathbf{y}})_q\}$  as the min of fp and fn totals in that interval.

# L1 relaxation interpretation

Our proposed loss function is

$$\text{AUM}(\hat{\mathbf{y}}) = \sum_{q=2}^{Q-1} [\tau(\hat{\mathbf{y}})_q - \tau(\hat{\mathbf{y}})_{q-1}] m(\hat{\mathbf{y}})_q.$$

It is an L1 relaxation of the following non-convex **Sum of Min(FP,FN)** function,

$$\text{SM}(\hat{\mathbf{y}}) = \sum_{q=2}^{Q-1} I[\tau(\hat{\mathbf{y}})_q \neq \tau(\hat{\mathbf{y}})_{q-1}] m(\hat{\mathbf{y}})_q = \sum_{q: \tau(\hat{\mathbf{y}})_q \neq \tau(\hat{\mathbf{y}})_{q-1}} m(\hat{\mathbf{y}})_q.$$

## Definition of data set, notations

- ▶ Let there be a total of  $B$  breakpoints in the error functions over all  $n$  labeled training examples.
- ▶ Each breakpoint  $b \in \{1, \dots, B\}$  is represented by the tuple  $(v_b, \Delta FP_b, \Delta FN_b, \mathcal{I}_b)$ , where the  $\mathcal{I}_b \in \{1, \dots, n\}$  is an example index, and there are changes  $\Delta FP_b, \Delta FN_b$  at predicted value  $v_b \in \mathbb{R}$  in the error functions.
- ▶ For example in binary classification, there are  $B = n$  breakpoints (same as the number of labeled training examples); for each breakpoint  $b \in \{1, \dots, B\}$  we have  $v_b = 0$  and  $\mathcal{I}_b = b$ . For breakpoints  $b$  with positive labels  $y_b = 1$  we have  $\Delta FP = 0, \Delta FN = -1$ , and for negative labels  $y_b = -1$  we have  $\Delta FP = 1, \Delta FN = 0$ .
- ▶ In changepoint detection we have more general error functions, which may have more than one breakpoint per example.

# Proposed algorithm uses sort to compute AUM and directional derivatives

- 1: **Input:** Predictions  $\hat{\mathbf{y}} \in \mathbb{R}^n$ , breakpoints in error functions  $v_b, \Delta FP_b, \Delta FN_b, \mathcal{I}_b$  for all  $b \in \{1, \dots, B\}$ .
  - 2: Zero the  $AUM \in \mathbb{R}$  and directional derivatives  $\mathbf{D} \in \mathbb{R}^{n \times 2}$ .
  - 3:  $t_b \leftarrow v_b - \hat{y}_{\mathcal{I}_b}$  for all  $b$ .
  - 4:  $s_1, \dots, s_B \leftarrow \text{SORTEDINDICES}(t_1, \dots, t_B)$ .
  - 5: Compute  $\underline{FP}_b, \overline{FP}_b, \underline{FN}_b, \overline{FN}_b$  for all  $b$  using  $s_1, \dots, s_B$ .
  - 6: **for**  $b \in \{2, \dots, B\}$  **do**
  - 7:    $AUM += (t_{s_b} - t_{s_{b-1}}) \min\{\underline{FP}_b, \overline{FN}_b\}$ .
  - 8: **for**  $b \in \{1, \dots, B\}$  **do**
  - 9:    $\mathbf{D}_{\mathcal{I}_b, 1} += \min\{\overline{FP}_b, \overline{FN}_b\} - \min\{\overline{FP}_b - \Delta FP_b, \overline{FN}_b - \Delta FN_b\}$
  - 10:    $\mathbf{D}_{\mathcal{I}_b, 2} += \min\{\underline{FP}_b + \Delta FP_b, \underline{FN}_b + \Delta FN_b\} - \min\{\underline{FP}_b, \underline{FN}_b\}$
  - 11: **Output:** AUM and matrix  $\mathbf{D}$  of directional derivatives.
- Overall  $O(B \log B)$  time due to sort.
